

How Bikes Move: A Pedal-Powered Adventure

Have you ever ridden a bike? Bikes are fun and can take you to many places. But how do bikes move? Let's find out!

A bike moves when you pedal. When you push down on the pedals, you make the bike's wheels turn. The pedals are connected to a chain. The chain is like a big loop that goes around gears. These gears help make the bike go fast or slow.

The bike has two wheels. The front wheel helps steer. When you turn the handlebars, the front wheel turns, and you can go left or right. The back wheel is what pushes the bike forward when you pedal.

Bikes also have brakes. When you squeeze the brake handles on the handlebars, the bike slows down or stops. Brakes are important for keeping you safe.

Tires on the bike are also important. They are filled with air and help you ride smoothly over bumps and holes in the road. Good tires make for a smoother and safer ride.

Did you know that your body helps the bike move too? When you sit on the bike and pedal, your legs become part of the bike! Your energy makes the bike go. Bikes are not just for fun. They are good for the environment too. They don't use gas like cars. This means they don't make the air dirty. Riding a bike is a clean way to travel.

Now you know how bikes move! Next time you ride, think about all the parts working together to help you go places.
